13 Modules, Six Functional Boundaries

The Simog ecosystem is a Maven-structured application. While physically modularized, its logical architecture requires grouping into functional tiers to understand the flow of data from external consumers down to the legacy persistence layers.

The Dependency Gravity Well

SimogCommon – The central dependency hub and primary reverse-engineering target.

Almost every higher-level module is tightly coupled to this core, requiring it for domain orchestration, database operations, and validation.

Key Classes

- `it.avlp.simog.db.AccessiDB`
- `it.avlp.simog.garamanager.GaraManager`
- `it.avlp.simog.garamanager.lotto.LottoManager`
- `it.avlp.simog.util.SimogProperties`

The Build and Schema Foundation

The system build is properly module-structured, yet the Java level constraints explicitly lock the ecosystem into a legacy baseline.

The Integration Onion: Penetrating the Core

External integration flows do not hit business logic directly. They traverse a deliberate sequence of endpoint termination, session validation, and proxy translation before invoking the internal SimogCommon managers.

Centralizing the Service Consumers

Insight: SimogWSCommon bridges external contract semantics with internal manager-based logic, serving as the technical session handler for all service consumers.

Analyzing the Integration Surfaces

The service API is heavily operational, fractured into three distinct endpoints to support substantial, yet highly specific, machine-to-machine interoperability profiles.

	SimogWSPDD	SimogWSAGG	SimogWSTED
Scope	Broad procurement operations.	Aggregator & Initiative flows.	TED publication flows.
Profile	High-contract integration surface.	Specialized interoperable surface.	Isolated integration boundary.
Key Flows	Create, update, and consult flows for procurement records.	Initiative communication and specialized aggregator workflows.	Delta management, verification, and cancellation via SimogTEDCommon.

Human Interfaces and Workflow Abstraction

Insight: While SimogWeb is a broad, legacy-style controller module, SimogFlusso indicates that workflow logic is explicitly recognized as a first-class architectural concern.

Authentication Evolution & Sedimentation

The coexistence of old and new login proxy paths within SimogAVCPLogin—abstracting local, remote, and IAA authentication—leaves a clear geological record of the system's architectural evolution.

The Operational Batch Subsystem

Batch integration via SimogMassLoader operates independently of the web and WS endpoints. It is operationally significant for procurement XML flows, functioning as a primary ingestion engine rather than just an internal utility.

The Bounded TED Subsystem

SimogTEDCommon represents a shift in internal design. It establishes a clear, bounded integration area dedicated entirely to TED processes, distinct from the generic domain orchestration found in the core.

Architectural Evolution Matrix

The Legacy Core (SimogCommon)

Tightly Coupled / Central Hub 

Manual JDBC access & SQL generation 

Generic managers (Tenders, Lots, Docs)

Deeply entrenched legacy constraints

The Modern Boundary (SimogTEDCommon)

 Isolated / Bounded Context

 Structured JPA entities & Repositories
(`persistence.xml`)

Highly specific TED operations

Modernized, explicit persistence model

Synthesis: A direct comparison reveals clear architectural sedimentation. The system has evolved from manual SQL generation within massive manager classes toward explicit, repository-based JPA persistence models.

The Modernization Baseline

The Simog ecosystem is not static. By mapping its structural boundaries—from the dense gravity well of the legacy core to the structured boundaries of the TED subsystem—we define the precise baseline required for targeted, surgical modernization.
